Empirical Proof Record — **INCONCLUSIVE**

Proof ID: 4c3790002fa45821c42b2b6fa065f424...

Created: 2026-05-23T23:10:38.020333+00:00

1. Claim

A partial cue of a SEEN experience recalls its full content better than a partial cue of a never-seen item: $\text{memory_lift} = \text{mean}(\text{recall}|\text{seen}) - \text{mean}(\text{recall}|\text{never-seen}) > 0$. Both arms get the same impoverished cue, so this isolates path-dependent memory from deterministic re-derivation.

- **Operationalisation:** Stream 6 seen items; never stream 2 control items. Probe partial cues (first 40% of words) of 6 seen and 2 control items. $\text{recall} = \text{Jaccard}(\text{concepts}(\text{partial cue}), \text{concepts}(\text{full item}))$. $\text{memory_lift} = \text{mean}(\text{recall}|\text{seen}) - \text{mean}(\text{recall}|\text{control})$; decided **VALIDATED** iff $\text{lift} > 0$ with a significant $\text{seen} > \text{control}$ Mann-Whitney.
- **Threshold:** $\text{memory_lift} > 0.0$ jaccard
- **H0:** $\text{H0: memory_lift} \leq 0$ — a seen partial cue recalls no better than a never-seen one; 'recall' is deterministic re-derivation
- **H1:** $\text{H1: memory_lift} > 0$ — prior exposure completes the partial cue; path-dependent memory beyond re-derivation

2. Verdict

INCONCLUSIVE — observed -0.12069518315648342

$\text{memory_lift} -0.1207 = \text{seen recall } 0.2578 \text{ (n=6)} - \text{control recall } 0.3785 \text{ (n=2)}$; partial cue = first 40% of words; **INCONCLUSIVE** — too few valid probes per arm

3. Evidence

Pillar	Statistic	Value	95% CI	Library
0.flow.cued_recall	memory_lift	-0.12069518315648342	—	ophamin 0.115.2
